LVDT DISPLACEMENT TRANSDUCERS

Innovation In Motion
The Penny+Giles range of rugged, high integrity LVDT displacement transducers are designed for operation in harsh automotive and industrial environments. The design elements employed have evolved from the technology and experience gained over 40 successful years in the aerospace/military sensor market, where performance and reliability under extreme operating conditions are paramount.

For an explanation of how LVDT's operate, see page 10.

**High accuracy system performance**

These LVDT displacement transducers have been designed primarily for use in the difference over sum (or ratiometric) configuration to provide high system accuracy performance where the output is virtually unaffected by temperature and supply changes. As the sum of the secondary output coil voltage \((V_a + V_b)\) is nominally constant throughout the stroke range, Penny+Giles LVDT’s can be employed for system error detection in high integrity systems. Alternatively, the LVDT’s can be used in the differential output configuration, with lower system accuracy.

For optimum performance of these LVDT’s we recommend the use of the purpose designed Signal Conditioning Module on page 8. The Penny+Giles LVDT and SCM module are designed to make using an LVDT as simple as using a linear potentiometer.

### Features
- No contact between the sensing elements
- Infinite resolution
- Absolute measurement
- Excellent repeatability
- Small transducer body length to stroke ratio
- Welded and vacuum brazed stainless steel construction
- Sealed to IP66
- Temperature range -35°C to +125°C
- High integrity coil, screen and connection assemblies
- Screened and sheathed interface cable
- Temperature error less than 35ppm/°C

### Benefits
- Virtually infinite life and fast dynamic response
- All displacement will be sensed
- No loss of position on power down
- Can perform very precise go/no-go applications
- Minimal operational footprint and weight
- Maximum reliability in hostile environments
- High performance in electrically noisy environments
- Maximises system accuracy

### Selection Guide
Penney+Giles offers the widest choice of options to suit your application.

**AF111 LVDT Transducer**  Page 4

The AF111 range is ideally suited to a number of industrial applications such as vehicle research, test rigs and OEM machinery.
Separate signal conditioning
By keeping the signal conditioning electronics away from the transducer the full potential of the LVDT is realised and not compromised by the presence of sensitive electronics. The result is a more reliable transducer solution, easily installed, adjusted and with a greater choice of signal inputs and outputs. The electronics have been tested to operate 25 metres from the LVDT, with the output driving 240 metres of cable.

Choice of mounting
Penny+Giles LVDT’s are offered with two standard mounting configurations. Model AF111 has a conventional threaded core attachment, with a body suitable for clamp mounting. Model AF145 utilises the popular self aligning bearing mounting style which can accommodate minor misalignment at the mounting attachments. Model AF145 also includes an outer sleeve, protecting the movable core whilst enhancing the rigidity of the transducer during operation.

Total reliability
The LVDT transducer system provides a highly reliable solution for position sensing, particularly in hostile environments. The contactless operating principle allows a fit and forget installation so that zero maintenance programmes can be incorporated within plant service schedules.

In stock availability
These LVDT displacement transducers are designed to provide the user with the most popular choice of mounting styles for a wide range of industrial applications. Stroke ranges from 5mm to 150mm are available from stock, so call your nearest sales office for the latest information.

Custom design
For larger scale users, we offer a custom design service which can customise either the mounting arrangement or shaft assembly to suit a specific system requirement.

AF145 LVDT Transducer Page 6
The AF145 range is suited to harsh automotive and industrial environments, with a compact body length and an outer sliding sleeve design which enhances the transducer rigidity over its operating range.

Conditioning Module - SCM100 Page 8
The SCM100 module is designed to operate the Penny+Giles range of LVDTs and provides outputs of 0-5, 0-10, ±10Vdc or 4-20mA. The module has span and null adjustment features to aid the installation of the LVDT.

LVDT panel indicators - DML300 series
Designed specifically for use with LVDT transducers.

Please ask for the separate brochure which details the features of the range.
The AF111 range of high accuracy LVDT displacement transducers have been designed primarily for use in the ratiometric configuration and have a compact size, with stroke lengths from 5mm to 150mm. Suitable for clamp mounting, the AF111 range have a threaded, unguided core assembly to simplify installation. Suited to numerous industrial applications, such as vehicle research, test rigs and OEM machinery.

**ELECTRICAL CONNECTIONS**

5 flying leads 24AWG, screened and sleeved 500mm long

**Phasing notes**

1. **High accuracy Ratiometric mode**
   When the LVDT is connected to the SCM100 module, there is no requirement to determine the phasing of the output to the input. The high performance circuit of the SCM100 determines all relevant parameters and supplies dc outputs as shown on page 8.

2. **Lower accuracy Differential mode**
   In this mode, the LVDT is used without the SCM100 module and could be connected to a third party signal conditioning module. With the black and blue leads common, the output on the yellow lead will be in-phase with the red lead (input) as the shaft retracts from the null position.

SCM100/.....
LVDT principle

The LVDT consists of a primary winding, two secondary windings and a separate, movable high permeability core (Fig A). When the primary winding is driven with an a.c. voltage a corresponding a.c. voltage is induced in the two secondary windings, in proportion to the position of the movable core. The secondary windings are connected in series opposition to form the transformer secondary (Fig B).

When the core is centered with respect to the two secondary windings, they will have the same magnitude of induced output voltages, but the polarity (or phasing) will be opposite.

When the core is displaced from this null position, the output amplitude on one secondary coil (Va) increases, while the output amplitude in the other coil (Vb) decreases (Fig C). These voltages can be used individually or combined to produce an output signal proportional to position, dependant upon the method of demodulation used. The two main methods used are described below.

Ratiometric operation

A high accuracy method of translating the LVDT output is to measure the secondary voltages independently to generate a ratio of the difference divided by the sum of these values.

\[ \text{Ratio} = \frac{V_a - V_b}{V_a + V_b} \]  

(Fig. D)

This configuration is commonly referred to as ratiometric operation and will provide much higher system accuracy performance than operation in the differential mode.

What is an LVDT?

LVDT is the acronym for Linear Variable Differential Transformer. The LVDT is a non-contacting linear displacement transducer which works on a principle of mutual inductance, producing an electrical signal which is proportional to a separate moving core (or armature). The fundamental advantages of LVDT transducers are their high degree of robustness, infinite resolution and ability to operate at high temperatures and in extreme environments.
Ratiometric operation provides:

- Improved immunity to LVDT supply voltage and frequency variations
- Improved immunity to errors due to temperature effects on LVDT sensitivity
- Improved frequency and phase response
- Improved immunity to common-mode noise on LVDT lines
- Improved transducer interchangeability

Additionally, the sum of the secondary output voltages (Va + Vb) is nominally constant throughout the LVDT stroke range, so it can be used for system error detection in high integrity systems.

To operate in the ratiometric mode requires a five or six wire, centre-tapped LVDT specifically designed for the purpose, as with Penny+ Giles AF145 and AF111 LVDT’s. Penny+ Giles recommend the use of the SCM100 LVDT driver or DML300 LVDT Driver/Panel Indicator, which are specifically designed to operate in this mode.

**Differential operation**

LVDTs are normally available with either four or five wires, where the extra wire is the centre-tap in the output. When operating in the differential mode, this centre-tap connection is often not used.

The output is taken across the whole transformer secondary, (see Fig. B). In this connection configuration, when the core is displaced from the centre null position, the output will increase in-phase with the input in one direction and anti-phase with the input in the other.

To derive the position from the LVDT, a modulator is required to provide the primary ac voltage in conjunction with a demodulator to translate the in-phase component transformer secondary output (Fig. E) to a dc signal proportional to position.

When using LVDT’s in this differential mode the output will be directly affected by changes in supply voltage, operating temperature and supply frequency; and is therefore of lower accuracy.

**Comparisons**

LVDTs operating in the differential mode will typically provide a temperature coefficient of sensitivity of up to 500ppm/°C.

LVDTs which have been designed to operate in the ratiometric mode use specialist winding techniques which achieve figures almost an order magnitude better - typically as low as 12ppm/°C. This is comparable with linear potentiometers (20 to 40ppm/°C).

An additional major benefit of this special ratiometric winding technique is the reduced body-to-stroke length ratio for devices over 25mm stroke. Typically values of between 30 and 40% reduction in LVDT body length can be achieved using this technique.
